Software

EZCSV
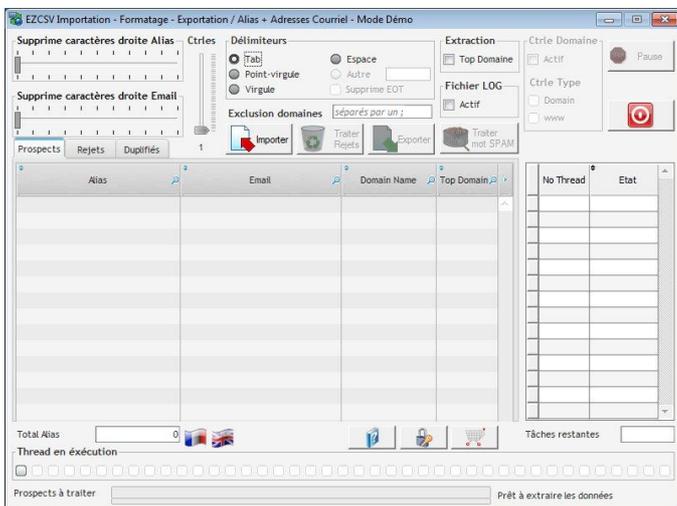

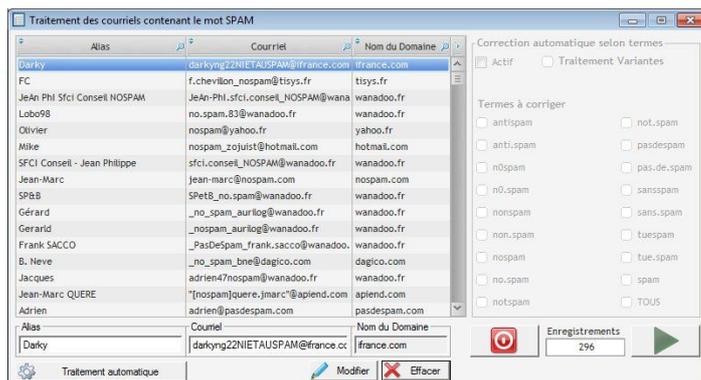

IIM SERVICES AGENCY

Import, format, clean, verify and export validated email addresses.

EZCSV has been developed in order to answer a need of formatting and verifying email addresses coming from bought lists or created through Internet. They usually contain many incorrect addresses or contaminated with anti-spam words. The software easily import email addresses through a file of type .CSV and also has several options to correct the wrong email addresses basing itself on the existing domains.

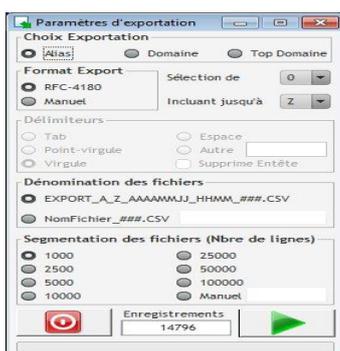

The main window is the heart of the software. It does allow importing data and setting up the parameters to handle the email addresses according to your needs. You also have access from this window to the handling of rejected email addresses, export, and also to the treatment of the contaminated emails with the word SPAM.

Checking handles can be done in parallel threads, up to 40 channels running at the same time in order to verify if the domain bounded to the email address exists or not.

The handling of contaminated email addresses can be done either manually or automatically. 17 different options are available to detect the word SPAM, and 16 variations can also be applied. All the permutations are then checked with the chosen optional terms.

Most of the variations are detected and corrected. In some cases, the software detects wrong addresses that can not be corrected and deletes them automatically from your database.

The export parameters do allow you to choose the generating mode of the file, according to the norm RFC-4180, or manually to meet your requirements.

You can select the quantity of addresses to export per file, their starting and ending letters, growing by alphabetical order, and the file name.
